

Robotics

Kinematics

*Kinematic map, Jacobian, inverse kinematics
as optimization problem, motion profiles,
trajectory interpolation, multiple simultaneous
tasks, special task variables,
configuration/operational/null space,
singularities*

Marc Toussaint
U Stuttgart

- Two “types of robotics”:
 - 1) Mobile robotics – is all about localization & mapping
 - 2) Manipulation – is all about interacting with the world[0) Kinematic/Dynamic Motion Control: same as 2) without ever making it to interaction..]
- Typical manipulation robots (and animals) are kinematic trees
Their pose/state is described by all joint angles

Basic motion generation problem

- Move all joints in a coordinated way so that the endeffector makes a desired movement

01-kinematics: `./x.exe -mode 2/3/4`

Outline

- Basic 3D geometry and notation
- Kinematics: $\phi : q \mapsto y$
- Inverse Kinematics: $y^* \mapsto q^* = \min_q \|y^* - \phi(q)\| + \|\Delta q\|_W$
- Basic motion heuristics: Motion profiles
- Additional things to know
 - Many simultaneous task variables
 - Singularities, null space,

Basic 3D geometry & notation

Pose (position & orientation)

- A *pose* is described by a translation $p \in \mathbb{R}^3$ and a rotation $R \in SO(3)$
 - R is an *orthonormal* matrix (orthogonal vectors stay orthogonal, unit vectors stay unit)
 - $R^{-1} = R^\top$
 - columns and rows are orthogonal unit vectors
 - $\det(R) = 1$
 - $R = \begin{pmatrix} R_{11} & R_{12} & R_{13} \\ R_{21} & R_{22} & R_{23} \\ R_{31} & R_{32} & R_{33} \end{pmatrix}$

Frame and coordinate transforms

- Let $(o, e_{1:3})$ be the world frame, $(o', e'_{1:3})$ be the body's frame. The new basis vectors are the *columns* in R , that is, $e'_1 = R_{11}e_1 + R_{21}e_2 + R_{31}e_3$, etc,
- x = coordinates in world frame $(o, e_{1:3})$
 x' = coordinates in body frame $(o', e'_{1:3})$
 p = coordinates of o' in world frame $(o, e_{1:3})$

$$x = p + Rx'$$

Rotations

- Rotations can alternatively be represented as
 - Euler angles – NEVER DO THIS!
 - Rotation vector
 - Quaternion – default in code
- See the “geometry notes” for formulas to convert, concatenate & apply to vectors

Homogeneous transformations

- x^A = coordinates of a point in frame A
 x^B = coordinates of a point in frame B
- Translation and rotation: $x^A = t + Rx^B$
- Homogeneous transform $T \in \mathbb{R}^{4 \times 4}$:

$$T_{A \rightarrow B} = \begin{pmatrix} R & t \\ 0 & 1 \end{pmatrix}$$

$$x^A = T_{A \rightarrow B} x^B = \begin{pmatrix} R & t \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x^B \\ 1 \end{pmatrix} = \begin{pmatrix} Rx^B + t \\ 1 \end{pmatrix}$$

in homogeneous coordinates, we append a 1 to all coordinate vectors

Is $T_{A \rightarrow B}$ forward or backward?

- $T_{A \rightarrow B}$ describes the translation and rotation of *frame* B relative to A
That is, it describes the forward FRAME transformation (from A to B)
- $T_{A \rightarrow B}$ describes the coordinate transformation from x^B to x^A
That is, it describes the backward COORDINATE transformation
- Confused? Vectors (and frames) transform *covariant*, coordinates *contra-variant*. See “geometry notes” or Wikipedia for more details, if you like.

Composition of transforms

$$T_{W \rightarrow C} = T_{W \rightarrow A} T_{A \rightarrow B} T_{B \rightarrow C}$$

$$x^W = T_{W \rightarrow A} T_{A \rightarrow B} T_{B \rightarrow C} x^C$$

Kinematics

Kinematics

- A *kinematic structure* is a graph (usually tree or chain) of rigid **links** and **joints**

$$T_{W \rightarrow \text{eff}}(q) = T_{W \rightarrow A} T_{A \rightarrow A'}(q) T_{A' \rightarrow B} T_{B \rightarrow B'}(q) T_{B' \rightarrow C} T_{C \rightarrow C'}(q) T_{C' \rightarrow \text{eff}}$$

Joint types

- Joint transformations: $T_{A \rightarrow A'}(q)$ depends on $q \in \mathbb{R}^n$

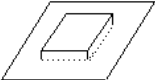

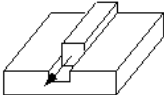

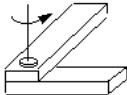

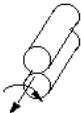

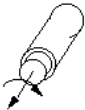

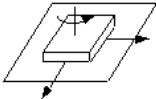

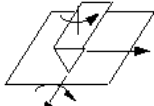

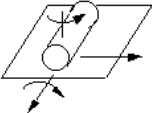

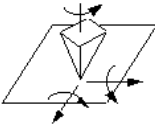

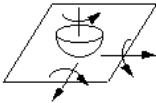

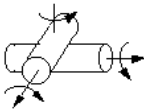

revolute joint: joint angle $q \in \mathbb{R}$ determines rotation about x -axis:

$$T_{A \rightarrow A'}(q) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos(q) & -\sin(q) & 0 \\ 0 & \sin(q) & \cos(q) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

prismatic joint: offset $q \in \mathbb{R}$ determines translation along x -axis:

$$T_{A \rightarrow A'}(q) = \begin{pmatrix} 1 & 0 & 0 & q \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

others: screw (1dof), cylindrical (2dof), spherical (3dof), universal (2dof)

 <p>Rigid (no motion)</p>	 <p>Prismatic</p>	 <p>Revolute</p>	 <p>Parallel Cylindrical</p>
 <p>Cylindrical</p>	 <p>Spherical</p>	 <p>Planar</p>	 <p>Edge Slider</p>
 <p>Cylindrical Slider</p>	 <p>Point Slider</p>	 <p>Spherical Slider</p>	 <p>Crossed Cylinder</p>

Kinematic Map

- For any joint angle vector $q \in \mathbb{R}^n$ we can compute $T_{W \rightarrow \text{eff}}(q)$ by *forward chaining* of transformations

$T_{W \rightarrow \text{eff}}(q)$ gives us the *pose* of the endeffector in the world frame

Kinematic Map

- For any joint angle vector $q \in \mathbb{R}^n$ we can compute $T_{W \rightarrow \text{eff}}(q)$ by *forward chaining* of transformations

$T_{W \rightarrow \text{eff}}(q)$ gives us the *pose* of the endeffector in the world frame

- The two most important examples for a *kinematic map* ϕ are

1) A point v on the endeffector transformed to world coordinates:

$$\phi_{\text{eff},v}^{\text{pos}}(q) = T_{W \rightarrow \text{eff}}(q) v \quad \in \mathbb{R}^3$$

2) A direction $v \in \mathbb{R}^3$ attached to the endeffector transformed to world:

$$\phi_{\text{eff},v}^{\text{vec}}(q) = R_{W \rightarrow \text{eff}}(q) v \quad \in \mathbb{R}^3$$

Where $R_{A \rightarrow B}$ is the rotation in $T_{A \rightarrow B}$.

Kinematic Map

- In general, a kinematic map is *any* (differentiable) mapping

$$\phi : q \mapsto y$$

that maps to *some arbitrary feature* $y \in \mathbb{R}^d$ of the pose $q \in \mathbb{R}^n$

Jacobian

- When we change the joint angles, δq , how does the effector position change, δy ?
- Given the kinematic map $y = \phi(q)$ and its Jacobian $J(q) = \frac{\partial}{\partial q} \phi(q)$, we have:

$$\delta y = J(q) \delta q$$

$$J(q) = \frac{\partial}{\partial q} \phi(q) = \begin{pmatrix} \frac{\partial \phi_1(q)}{\partial q_1} & \frac{\partial \phi_1(q)}{\partial q_2} & \cdots & \frac{\partial \phi_1(q)}{\partial q_n} \\ \frac{\partial \phi_2(q)}{\partial q_1} & \frac{\partial \phi_2(q)}{\partial q_2} & \cdots & \frac{\partial \phi_2(q)}{\partial q_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial \phi_d(q)}{\partial q_1} & \frac{\partial \phi_d(q)}{\partial q_2} & \cdots & \frac{\partial \phi_d(q)}{\partial q_n} \end{pmatrix} \in \mathbb{R}^{d \times n}$$

Jacobian for a rotational joint

- The i -th joint is located at $p_i = t_{W \rightarrow i}(q)$ and has rotation axis

$$a_i = R_{W \rightarrow i}(q) \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$$

- We consider an infinitesimal variation $\delta q_i \in \mathbb{R}$ of the i th joint and see how an endeffector position $p_{\text{eff}} = \phi_{\text{eff},v}^{\text{pos}}(q)$ and attached vector $a_{\text{eff}} = \phi_{\text{eff},v}^{\text{vec}}(q)$ change.

Jacobian for a rotational joint

Consider a variation δq_i
 \rightarrow the whole sub-tree rotates

$$\delta p_{\text{eff}} = [a_i \times (p_{\text{eff}} - p_i)] \delta q_i$$

$$\delta a_{\text{eff}} = [a_i \times a_{\text{eff}}] \delta q_i$$

\Rightarrow Position Jacobian:

$$J_{\text{eff},v}^{\text{pos}}(q) = \begin{pmatrix} [a_1 \times (p_{\text{eff}} - p_1)] \\ [a_2 \times (p_{\text{eff}} - p_2)] \\ \dots \\ [a_n \times (p_{\text{eff}} - p_n)] \end{pmatrix} \in \mathbb{R}^{3 \times n}$$

\Rightarrow Vector Jacobian:

$$J_{\text{eff},v}^{\text{vec}}(q) = \begin{pmatrix} [a_1 \times a_{\text{eff}}] \\ [a_2 \times a_{\text{eff}}] \\ \dots \\ [a_n \times a_{\text{eff}}] \end{pmatrix} \in \mathbb{R}^{3 \times n}$$

Jacobian

- To compute the Jacobian of some endeffector position or vector, we only need to know the position and rotation axis of each joint.
- The two kinematic maps ϕ^{pos} and ϕ^{vec} are the most important two examples – more complex geometric features can be computed from these, as we will see later.

Inverse Kinematics

Inverse Kinematics problem

- Generally, the aim is to find a robot configuration q such that $\phi(q) = y^*$
- Iff ϕ is invertible

$$q^* = \phi^{-1}(y^*)$$

- But in general, ϕ will not be invertible:

1) The pre-image $\phi^{-1}(y^*)$ may be empty: No configuration can generate the desired y^*

2) The pre-image $\phi^{-1}(y^*)$ may be large: many configurations can generate the desired y^*

Inverse Kinematics as optimization problem

- We formalize the inverse kinematics problem as an optimization problem

$$q^* = \underset{q}{\operatorname{argmin}} \|\phi(q) - y^*\|_C^2 + \|q - q_0\|_W^2$$

- The 1st term ensures that we find a configuration even if y^* is not exactly reachable

The 2nd term disambiguates the configurations if there are many $\phi^{-1}(y^*)$

Inverse Kinematics as optimization problem

$$q^* = \operatorname{argmin}_q \|\phi(q) - y^*\|_C^2 + \|q - q_0\|_W^2$$

- The formulation of IK as an optimization problem is very powerful and has many nice properties
- We will be able to take the limit $C \rightarrow \infty$, enforcing exact $\phi(q) = y^*$ if possible
- Non-zero C^{-1} and W corresponds to a regularization that ensures numeric stability
- Classical concepts can be derived as special cases:
 - Null-space motion
 - regularization; singularity robustness
 - multiple tasks
 - hierarchical tasks

Solving Inverse Kinematics

- The obvious choice of optimization method for this problem is Gauss-Newton, using the Jacobian of ϕ
- We first describe just one step of this, which leads to the classical equations for inverse kinematics using the local Jacobian...

Solution using the local linearization

- When using the local linearization of ϕ at q_0 ,

$$\phi(q) \approx y_0 + J (q - q_0) , \quad y_0 = \phi(q_0)$$

- We can derive the optimum as

$$\begin{aligned} f(q) &= \|\phi(q) - y^*\|_C^2 + \|q - q_0\|_W^2 \\ &= \|y_0 - y^* + J (q - q_0)\|_C^2 + \|q - q_0\|_W^2 \end{aligned}$$

$$\frac{\partial}{\partial q} f(q) = 0^\top = 2(y_0 - y^* + J (q - q_0))^\top C J + 2(q - q_0)^\top W$$

$$J^\top C (y^* - y_0) = (J^\top C J + W) (q - q_0)$$

$$q^* = q_0 + J^\# (y^* - y_0)$$

with $J^\# = (J^\top C J + W)^{-1} J^\top C = W^{-1} J^\top (J W^{-1} J^\top + C^{-1})^{-1}$ (*Woodbury identity*)

- For $C \rightarrow \infty$ and $W = \mathbf{I}$, $J^\# = J^\top (J J^\top)^{-1}$ is called *pseudo-inverse*
- W generalizes the metric in q -space
- C regularizes this pseudo-inverse (see later section on singularities)

“Small step” application

- This approximate solution to IK makes sense
 - if the local linearization of ϕ at q_0 is “good”
 - if q_0 and q^* are close
- This equation is therefore typically used to iteratively compute small steps in configuration space

$$q_{t+1} = q_t + J^\sharp(y_{t+1}^* - \phi(q_t))$$

where the target y_{t+1}^* moves smoothly with t

Example: Iterating IK to follow a trajectory

- Assume initial posture q_0 . We want to reach a desired endeff position y^* in T steps:

Input: initial state q_0 , desired y^* , methods ϕ^{pos} and J^{pos}

Output: trajectory $q_{0:T}$

```
1: Set  $y_0 = \phi^{\text{pos}}(q_0)$  // starting endeff position
2: for  $t = 1 : T$  do
3:    $y \leftarrow \phi^{\text{pos}}(q_{t-1})$  // current endeff position
4:    $J \leftarrow J^{\text{pos}}(q_{t-1})$  // current endeff Jacobian
5:    $\hat{y} \leftarrow y_0 + (t/T)(y^* - y_0)$  // interpolated endeff target
6:    $q_t = q_{t-1} + J^\#(\hat{y} - y)$  // new joint positions
7:   Command  $q_t$  to all robot motors and compute all  $T_{W \rightarrow i}(q_t)$ 
8: end for
```

01-kinematics: ./x.exe -mode 2/3

Example: Iterating IK to follow a trajectory

- Assume initial posture q_0 . We want to reach a desired endeff position y^* in T steps:

Input: initial state q_0 , desired y^* , methods ϕ^{pos} and J^{pos}

Output: trajectory $q_{0:T}$

```
1: Set  $y_0 = \phi^{\text{pos}}(q_0)$  // starting endeff position
2: for  $t = 1 : T$  do
3:    $y \leftarrow \phi^{\text{pos}}(q_{t-1})$  // current endeff position
4:    $J \leftarrow J^{\text{pos}}(q_{t-1})$  // current endeff Jacobian
5:    $\hat{y} \leftarrow y_0 + (t/T)(y^* - y_0)$  // interpolated endeff target
6:    $q_t = q_{t-1} + J^\#(\hat{y} - y)$  // new joint positions
7:   Command  $q_t$  to all robot motors and compute all  $T_{W \rightarrow i}(q_t)$ 
8: end for
```

01-kinematics: ./x.exe -mode 2/3

- Why does this not follow the interpolated trajectory $\hat{y}_{0:T}$ exactly?
 - What happens if $T = 1$ and y^* is far?

Two additional notes

- What if we linearize at some arbitrary q' instead of q_0 ?

$$\begin{aligned}\phi(q) &\approx y' + J (q - q') , \quad y' = \phi(q') \\ q^* &= \underset{q}{\operatorname{argmin}} \|\phi(q) - y^*\|_C^2 + \|q - q' + (q' - q_0)\|_W^2 \\ &= q' + J^\sharp (y^* - y') + (I - J^\sharp J) h , \quad h = q_0 - q'\end{aligned}\tag{1}$$

Note that h corresponds to the classical concept of *null space motion*

- What if we want to find the *exact* (local) optimum? E.g. what if we want to compute a big step (where q^* will be remote from q) and we cannot not rely only on the local linearization approximation?
 - Iterate equation (1) (optionally with a step size < 1 to ensure convergence) by setting the point y' of linearization to the current q^*
 - This is equivalent to the Gauss-Newton algorithm

Where are we?

- We've derived a basic motion generation principle in robotics from
 - an understanding of robot geometry & kinematics
 - a basic notion of optimality

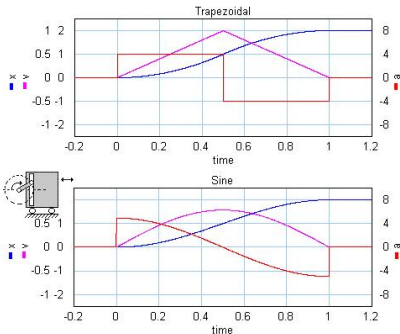

Where are we?

- We've derived a basic motion generation principle in robotics from
 - an understanding of robot geometry & kinematics
 - a basic notion of optimality
- In the remainder:
 - A. Heuristic motion profiles for simple trajectory generation
 - B. Extension to multiple task variables
 - C. Discussion of classical concepts
 - Singularity and singularity-robustness
 - Nullspace, task/operational space, joint space
 - “inverse kinematics” \leftrightarrow “motion rate control”

Heuristic motion profiles

Heuristic motion profiles

- Assume initially $x = 0, \dot{x} = 0$. After 1 second you want $x = 1, \dot{x} = 0$. How do you move from $x = 0$ to $x = 1$ in one second?

The sine profile $x_t = x_0 + \frac{1}{2}[1 - \cos(\pi t/T)](x_T - x_0)$ is a compromise for low max-acceleration and max-velocity

Taken from http://www.20sim.com/webhelp/toolboxes/mechatronics_toolbox/motion_profile_wizard/motionprofiles.htm

Motion profiles

- Generally, let's define a motion profile as a mapping

$$\text{MP} : [0, 1] \mapsto [0, 1]$$

with $\text{MP}(0) = 0$ and $\text{MP}(1) = 1$ such that the interpolation is given as

$$x_t = x_0 + \text{MP}(t/T) (x_T - x_0)$$

- For example

$$\text{MP}_{\text{ramp}}(s) = s$$

$$\text{MP}_{\text{sin}}(s) = \frac{1}{2}[1 - \cos(\pi s)]$$

Joint space interpolation

1) Optimize a desired final configuration q_T :

Given a desired final task value y_T , optimize a final joint state q_T to minimize the function

$$f(q_T) = \|q_T - q_0\|_{W/T}^2 + \|y_T - \phi(q_T)\|_C^2$$

- The metric $\frac{1}{T}W$ is consistent with T cost terms with step metric W .
- In this optimization, q_T will end up remote from q_0 . So we need to iterate Gauss-Newton, as described on slide 30.

2) Compute $q_{0:T}$ as interpolation between q_0 and q_T :

Given the initial configuration q_0 and the final q_T , interpolate on a straight line with a some motion profile. E.g.,

$$q_t = q_0 + \text{MP}(t/T) (q_T - q_0)$$

Task space interpolation

- 1) Compute $y_{0:T}$ as interpolation between y_0 and y_T :

Given a initial task value y_0 and a desired final task value y_T , interpolate on a straight line with a some motion profile. E.g,

$$y_t = y_0 + \text{MP}(t/T) (y_T - y_0)$$

- 2) Project $y_{0:T}$ to $q_{0:T}$ using inverse kinematics:

Given the task trajectory $y_{0:T}$, compute a corresponding joint trajectory $q_{0:T}$ using inverse kinematics

$$q_{t+1} = q_t + J^\sharp(y_{t+1} - \phi(q_t))$$

(As steps are small, we should be ok with just using this local linearization.)

peg-in-a-hole demo

Multiple tasks

Multiple tasks

Multiple tasks

Multiple tasks

- Assume we have m simultaneous tasks; for each task i we have:
 - a kinematic mapping $y_i = \phi_i(q) \in \mathbb{R}^{d_i}$
 - a current value $y_{i,t} = \phi_i(q_t)$
 - a desired value y_i^*
 - a precision ϱ_i (implying a task cost metric $C_i = \varrho_i \mathbf{I}$)

Multiple tasks

- Assume we have m simultaneous tasks; for each task i we have:
 - a kinematic mapping $y_i = \phi_i(q) \in \mathbb{R}^{d_i}$
 - a current value $y_{i,t} = \phi_i(q_t)$
 - a desired value y_i^*
 - a precision ϱ_i (implying a task cost metric $C_i = \varrho_i \mathbf{I}$)
- Each task contributes a term to the objective function

$$q^* = \operatorname{argmin}_q \|q - q_0\|_W^2 + \varrho_1 \|\phi_1(q) - y_1^*\|^2 + \varrho_2 \|\phi_2(q) - y_2^*\|^2 + \dots$$

Multiple tasks

- Assume we have m simultaneous tasks; for each task i we have:
 - a kinematic mapping $y_i = \phi_i(q) \in \mathbb{R}^{d_i}$
 - a current value $y_{i,t} = \phi_i(q_t)$
 - a desired value y_i^*
 - a precision ϱ_i (implying a task cost metric $C_i = \varrho_i \mathbf{I}$)
- Each task contributes a term to the objective function

$$q^* = \operatorname{argmin}_q \|q - q_0\|_W^2 + \varrho_1 \|\phi_1(q) - y_1^*\|^2 + \varrho_2 \|\phi_2(q) - y_2^*\|^2 + \dots$$

which we can also write as

$$q^* = \operatorname{argmin}_q \|q - q_0\|_W^2 + \|\Phi(q)\|^2$$

$$\text{where } \Phi(q) := \begin{pmatrix} \sqrt{\varrho_1} (\phi_1(q) - y_1^*) \\ \sqrt{\varrho_2} (\phi_2(q) - y_2^*) \\ \vdots \end{pmatrix} \in \mathbb{R}^{\sum_i d_i}$$

Multiple tasks

- We can “pack” together all tasks in one “big task” Φ .

Example: We want to control the 3D position of the left hand and of the right hand. Both are “packed” to one 6-dimensional task vector which becomes zero if both tasks are fulfilled.

- The big Φ is scaled/normalized in a way that
 - the desired value is always zero
 - the cost metric is \mathbf{I}
- Using the local linearization of Φ at q_0 , $J = \frac{\partial \Phi(q_0)}{\partial q}$, the optimum is

$$\begin{aligned} q^* &= \underset{q}{\operatorname{argmin}} \|q - q_0\|_W^2 + \|\Phi(q)\|^2 \\ &\approx q_0 - (J^\top J + W)^{-1} J^\top \Phi(q_0) = q_0 - J^\# \Phi(q_0) \end{aligned}$$

Multiple tasks

- We learnt how to “puppeteer a robot”
- We can handle many task variables (but specifying their precisions q_i becomes cumbersome...)
- In the remainder:
 - A. Classical limit of “hierarchical IK” and nullspace motion
 - B. What are interesting task variables?

Hierarchical IK & nullspace motion

- In the classical view, tasks should be executed *exactly*, which means taking the limit $\varrho_i \rightarrow \infty$ in some prespecified hierarchical order.
- We can rewrite the solution in a way that allows for such a hierarchical limit:
- One task plus “nullspace motion”:

$$\begin{aligned} f(q) &= \|q - a\|_W^2 + \varrho_1 \|J_1 q - y_1\|^2 \\ &\propto \|q - \hat{a}\|_{\widehat{W}}^2 \\ \widehat{W} &= W + \varrho_1 J_1^\top J_1, \quad \hat{a} = \widehat{W}^{-1}(W a + \varrho_1 J_1^\top y_1) = J_1^\# y_1 + (\mathbf{I} - J_1^\# J_1) a \\ J_1^\# &= (W/\varrho_1 + J_1^\top J_1)^{-1} J_1^\top \end{aligned}$$

- Two tasks plus nullspace motion:

$$\begin{aligned} f(q) &= \|q - a\|_W^2 + \varrho_1 \|J_1 q - y_1\|^2 + \varrho_2 \|J_2 q - y_2\|^2 \\ &= \|q - \hat{a}\|_{\widehat{W}}^2 + \|J_1 q - \Phi_1\|^2 \\ q^* &= J_1^\# y_1 + (\mathbf{I} - J_1^\# J_1)[J_2^\# y_2 + (\mathbf{I} - J_2^\# J_2)a] \\ J_2^\# &= (W/\varrho_2 + J_2^\top J_2)^{-1} J_2^\top, \quad J_1^\# = (\widehat{W}/\varrho_1 + J_1^\top J_1)^{-1} J_1^\top \end{aligned}$$

- etc...

Hierarchical IK & nullspace motion

- The previous slide did nothing but rewrite the nice solution $q^* = -J^\# \Phi(q_0)$ (for the “big” Φ) in a strange hierarchical way that allows to “see” nullspace projection
- The benefit of this hierarchical way to write the solution is that one can take the hierarchical limit $\varrho_i \rightarrow \infty$ and retrieve classical hierarchical IK
- The drawbacks are:
 - It is somewhat ugly
 - In practise, I would recommend regularization in any case (for numeric stability). Regularization corresponds to NOT taking the full limit $\varrho_i \rightarrow \infty$. Then the hierarchical way to write the solution is unnecessary. (However, it points to a “hierarchical regularization”, which might be numerically more robust for very small regularization?)
 - The general solution allows for arbitrary blending of tasks

What are interesting task variables?

The following slides will define 10 different types of task variables.
This is meant as a reference and to give an idea of possibilities...

Position

Position of some point attached to link i	
dimension	$d = 3$
parameters	link index i , point offset v
kin. map	$\phi_{iv}^{\text{pos}}(q) = T_{W \rightarrow i} v$
Jacobian	$J_{iv}^{\text{pos}}(q)_{\cdot k} = [k \prec i] a_k \times (\phi_{iv}^{\text{pos}}(q) - p_k)$

Notation:

- a_k, p_k are axis and position of joint k
- $[k \prec i]$ indicates whether joint k is between root and link i
- $J_{\cdot k}$ is the k th column of J

Vector

Vector attached to link i	
dimension	$d = 3$
parameters	link index i , attached vector v
kin. map	$\phi_{iv}^{\text{vec}}(q) = R_{W \rightarrow i} v$
Jacobian	$J_{iv}^{\text{vec}}(q) = A_i \times \phi_{iv}^{\text{vec}}(q)$

Notation:

- A_i is a matrix with columns $(A_i)_{\cdot k} = [k \prec i] a_k$ containing the joint axes or zeros
- the short notation “ $A \times p$ ” means that each *column* in A takes the cross-product with p .

Relative position

Position of a point on link i relative to point on link j	
dimension	$d = 3$
parameters	link indices i, j , point offset v in i and w in j
kin. map	$\phi_{iv jw}^{\text{pos}}(q) = R_j^{-1}(\phi_{iv}^{\text{pos}} - \phi_{jw}^{\text{pos}})$
Jacobian	$J_{iv jw}^{\text{pos}}(q) = R_j^{-1}[J_{iv}^{\text{pos}} - J_{jw}^{\text{pos}} - A_j \times (\phi_{iv}^{\text{pos}} - \phi_{jw}^{\text{pos}})]$

Derivation:

For $y = Rp$ the derivative w.r.t. a rotation around axis a is

$y' = Rp' + R'p = Rp' + a \times Rp$. For $y = R^{-1}p$ the derivative is

$y' = R^{-1}p' - R^{-1}(R')R^{-1}p = R^{-1}(p' - a \times p)$. (For details see

<http://ipvs.informatik.uni-stuttgart.de/mlr/marc/notes/3d-geometry.pdf>)

Relative vector

Vector attached to link i relative to link j	
dimension	$d = 3$
parameters	link indices i, j , attached vector v in i
kin. map	$\phi_{iv j}^{\text{vec}}(q) = R_j^{-1} \phi_{iv}^{\text{vec}}$
Jacobian	$J_{iv j}^{\text{vec}}(q) = R_j^{-1} [J_{iv}^{\text{vec}} - A_j \times \phi_{iv}^{\text{vec}}]$

Alignment

Alignment of a vector attached to link i with a reference v^*	
dimension	$d = 1$
parameters	link index i , attached vector v , world reference v^*
kin. map	$\phi_{iv}^{\text{align}}(q) = v^{*\top} \phi_{iv}^{\text{vec}}$
Jacobian	$J_{iv}^{\text{align}}(q) = v^{*\top} J_{iv}^{\text{vec}}$

Note: $\phi^{\text{align}} = 1 \leftrightarrow \text{align}$ $\phi^{\text{align}} = -1 \leftrightarrow \text{anti-align}$ $\phi^{\text{align}} = 0 \leftrightarrow \text{orthog.}$

Relative Alignment

Alignment a vector attached to link i with vector attached to j	
dimension	$d = 1$
parameters	link indices i, j , attached vectors v, w
kin. map	$\phi_{iv jw}^{\text{align}}(q) = (\phi_{jw}^{\text{vec}})^{\top} \phi_{iv}^{\text{vec}}$
Jacobian	$J_{iv jw}^{\text{align}}(q) = (\phi_{jw}^{\text{vec}})^{\top} J_{iv}^{\text{vec}} + \phi_{iv}^{\text{vec}\top} J_{jw}^{\text{vec}}$

Joint limits

Penetration of joint limits	
dimension	$d = 1$
parameters	joint limits $q_{\text{low}}, q_{\text{hi}}$, margin m
kin. map	$\phi_{\text{limits}}(q) = \frac{1}{m} \sum_{i=1}^n [m - q_i + q_{\text{low}}]^+ + [m + q_i - q_{\text{hi}}]^+$
Jacobian	$J_{\text{limits}}(q)_{1,i} = -\frac{1}{m} [m - q_i + q_{\text{low}} > 0] + \frac{1}{m} [m + q_i - q_{\text{hi}} > 0]$

$[x]^+ = x > 0 ? x : 0$ $[\dots]$: indicator function

Collision limits

Penetration of collision limits	
dimension	$d = 1$
parameters	margin m
kin. map	$\phi_{\text{col}}(q) = \frac{1}{m} \sum_{k=1}^K [m - p_k^a - p_k^b]^+$
Jacobian	$J_{\text{col}}(q) = \frac{1}{m} \sum_{k=1}^K [m - p_k^a - p_k^b > 0]$ $(-J_{p_k^a}^{\text{pos}} + J_{p_k^b}^{\text{pos}})^{\top} \frac{p_k^a - p_k^b}{ p_k^a - p_k^b }$

A collision detection engine returns a set $\{(a, b, p^a, p^b)_{k=1}^K\}$ of potential collisions between link a_k and b_k , with nearest points p_k^a on a and p_k^b on b .

Center of gravity

Center of gravity of the whole kinematic structure	
dimension	$d = 3$
parameters	(none)
kin. map	$\phi^{\text{cog}}(q) = \sum_i \text{mass}_i \phi_{ic_i}^{\text{pos}}$
Jacobian	$J^{\text{cog}}(q) = \sum_i \text{mass}_i J_{ic_i}^{\text{pos}}$

c_i denotes the center-of-mass of link i (in its own frame)

Homing

The joint angles themselves	
dimension	$d = n$
parameters	(none)
kin. map	$\phi_{\text{qitself}}(q) = q$
Jacobian	$J_{\text{qitself}}(q) = \mathbf{I}_n$

Example: Set the target $y^* = 0$ and the precision ϱ very low \rightarrow this task describes posture comfortness in terms of deviation from the joints' zero position. In the classical view, it induces "nullspace motion".

Task variables – conclusions

- There is much space for creativity in defining task variables! Many are extensions of ϕ^{pos} and ϕ^{vec} and the Jacobians combine the basic Jacobians.
- What the *right* task variables are to design/describe motion is a very hard problem! In what task space do humans control their motion? Possible to learn from data (“task space retrieval”) or perhaps via Reinforcement Learning.
- In practice: Robot motion design (including grasping) may require cumbersome hand-tuning of such task variables.

Discussion of classical concepts

- Singularity and singularity-robustness
- Nullspace, task/operational space, joint space
- “inverse kinematics” \leftrightarrow “motion rate control”

Singularity

- In general: A matrix J **singular** $\iff \text{rank}(J) < d$
 - rows of J are linearly dependent
 - dimension of image is $< d$
 - $\delta y = J\delta q \Rightarrow$ dimensions of δy limited
 - Intuition: arm fully stretched

Singularity

- In general: A matrix J **singular** $\iff \text{rank}(J) < d$
 - rows of J are linearly dependent
 - dimension of image is $< d$
 - $\delta y = J\delta q \Rightarrow$ dimensions of δy limited
 - Intuition: arm fully stretched

- Implications:

$$\det(JJ^\top) = 0$$

- \rightarrow pseudo-inverse $J^\top(JJ^\top)^{-1}$ is ill-defined!
- \rightarrow inverse kinematics $\delta q = J^\top(JJ^\top)^{-1}\delta y$ computes “infinite” steps!

- **Singularity robust pseudo inverse** $J^\top(JJ^\top + \epsilon\mathbf{I})^{-1}$

The term $\epsilon\mathbf{I}$ is called **regularization**

- Recall our general solution (for $W = \mathbf{I}$)

$$J^\# = J^\top(JJ^\top + C^{-1})^{-1}$$

is already singularity robust

Null/task/operational/joint/configuration spaces

- The space of all $q \in \mathbb{R}^n$ is called **joint/configuration space**
The space of all $y \in \mathbb{R}^d$ is called **task/operational space**
Usually $d < n$, which is called **redundancy**

Null/task/operational/joint/configuration spaces

- The space of all $q \in \mathbb{R}^n$ is called **joint/configuration space**
The space of all $y \in \mathbb{R}^d$ is called **task/operational space**
Usually $d < n$, which is called **redundancy**
- For a desired endeffector state y^* there exists a whole manifold (assuming ϕ is smooth) of joint configurations q :

$$\text{nullspace}(y^*) = \{q \mid \phi(q) = y^*\}$$

- We found earlier that

$$\begin{aligned} q^* &= \underset{q}{\operatorname{argmin}} \|q - a\|_W^2 + \varrho \|Jq - y^*\|^2 \\ &= J^\# y^* + (\mathbf{I} - J^\# J)a, \quad J^\# = (W/\varrho + J^\top J)^{-1} J^\top \end{aligned}$$

In the limit $\varrho \rightarrow \infty$ it is guaranteed that $Jq = y^*$ (we are exact on the manifold). The term a introduces additional “nullspace motion”.

Inverse Kinematics and Motion Rate Control

Some clarification of concepts:

- The notion “kinematics” describes the mapping $\phi : q \mapsto y$, which usually is a many-to-one function.
- The notion “inverse kinematics” in the strict sense describes some mapping $g : y \mapsto q$ such that $\phi(g(y)) = y$, which usually is non-unique or ill-defined.
- In practice, one often refers to $\delta q = J^\# \delta y$ as **inverse kinematics**.
- When iterating $\delta q = J^\# \delta y$ in a control cycle with time step τ (typically $\tau \approx 1 - 10$ msec), then $\dot{y} = \delta y / \tau$ and $\dot{q} = \delta q / \tau$ and $\dot{q} = J^\# \dot{y}$. Therefore the control cycle effectively controls the endeffector velocity—this is why it is called **motion rate control**.
